20. ABSTRACT (Continue on reverse side if necessary and identify by block number)  Similarity retrieval from a large pictorial database can be much more efficient by encoding the original database into certain convenient formats. Generalized hypercube (GH) encoding is one such technique. To optimize GH encoding, a heuristic approach has been formulated. Two optimization problems have been considered here: First, given the handle length m, find the optimal GH <sub>m</sub> encoding. Second, given the threshold density, find the optimal GH encoding such that each generated hypercube has a density no less than a threshold density.

## A HEURISTIC METHOD OF OPTIMAL GENERALIZED HYPERCUBE ENCODING FOR PICTORIAL DATABASES

### INTRODUCTION

In similarity/retrieval from a pictorial database [1], pattern recognition [2,4], and clustering analysis, it is often desired to find the set of database records (or set of patterns, n-dimensional feature vectors, etc.) that are most similar to a test record (or test pattern, test feature vector, etc.). In the case of large databases (or patterns, clusters), it is very useful to encode the original database into certain convenient format in order to facilitate similarity retrieval and updating.

In this report, we shall consider one such technique called "Generalized Hypercube" encoding [3] and describe a heuristic method of generating minimum number of GH encoded tuples.

### GENERALIZED HYPERCUBE ENCODING

Given a set of points  $S = \{ p_1, p_2, \dots, p_k \}$  in n-dimensional space, where  $p_i = (x_1, x_2, \dots, x_n)$  denotes a point in S, we can have a family of n-dimensional GH codes. For each  $m$ ,  $1 \leq m \leq n + 1$ , the  $GH_m$  codes are:

$$(x_1, \dots, x_{m-1}; a_m, \dots, a_n; b_m, \dots, b_n),$$

where  $(x_1, x_2, \dots, x_{m-1}, z_m, \dots, z_n)$  is in S for some coordinates,  $z_m, \dots, z_n$ ; and  $a_j = \min \{ y_j : \text{for some coordinates, } z_k, (x_1, \dots, x_{m-1}, z_m, \dots, y_j, \dots, z_n) \text{ in } S \}$ ,  $b_j = \max \{ y_j : \text{for some coordinates, } z_k, (x_1, \dots, x_{m-1}, z_m, \dots, y_j, \dots, z_n) \text{ in } S \}$ .

When  $m = 1$ , we are simply using the smallest n-dimensional hypercube containing S as the GH code. When  $m = n+1$ , the original point set S is used as the GH code. Other in-between values of m give GH codes of various levels of details.

For example, if point set  $S = \{(1,1,3),(1,1,5),(1,2,1),(1,2,4),(2,3,6)\}$ ,  $GH_1$  is  $\{(1,1,1;2,3,6)\}$ .  $GH_2$  is  $\{(1;1,1;2,5),(2;3,6;3,6)\}$ .  $GH_3$  is  $\{(1,1;3;5),(1,2;1;4),(2,3;6;6)\}$ .  $GH_4$  is S itself. It should be noted that other GH codes can be generated, if we permute the coordinates. The previous example we have  $\{(3;1,1;1,1),(5;1,1;1,1),(1;1,2;1,2),(6;2,3;2,3)\}$ .

Therefore, it is important to select carefully the coordinates on which the GH encoding technique can be applied, i.e. to generate a minimum number of GH encoded tuples the problem reduces to select a special "handle" set. It is easy to see that once a handle vector has been selected, the GH encoding is unique.

In this report we shall describe the following heuristic methods for problems:

- Select a handle set  $\{i_1, i_2, \dots, i_{m-1}\}$  from  $\{1, 2, \dots, n\}$  so that the least number of GH encoded tuples are generated.
- Suppose we define the density of a hypercube H as the number of data points in H, divided by total number of lattice integers.). For example the hypercube (1,1,1;2,3,6) previously described has a density of  $5/2 \cdot 3 \cdot 6 = 0.1388$ . Intuitively, we would like to generate hypercubes having high densities. Therefore Problem 2 can be stated as follows:

Given a threshold density  $t$ ,  $0 \leq t \leq 1.0$ , find optimal GH encoding such that each hypercube has density no less than  $t$ .

## PROBLEM 1

Given  $m$ , the method of choosing  $m-1$  handles which will generate optimal GH<sub>m</sub> codes for a point set  $S$  is based on the following ideas:

- For each handle (column)  $i$ , ( $i = 1, 2, \dots, n$ ) consider vector  $V_i = (x_{1i}, x_{2i}, \dots, x_{ki})$  where  $k$  is the number of points in the set  $S$ . Among the elements  $x_{i1}, x_{i2}, \dots, x_{ik}$  those having the same value are grouped together and their associated points (in  $S$ ) will consist of disjoint groups, say,  $G_{1i}, G_{2i}, \dots, G_{\ell i}$ . Define the count (or cardinality) of  $G_{ji} = C_j(i)$ . We next compute a measure of the priority of the  $i$ th column  $p_i$ .

$$\bullet p_i = \sum_{j=1}^{\ell} [C_j(i)-1]^2.$$

Intuitively, we ignore those groups having only one element and put heavier weight to those groups having more than one element. Obviously, there are many other ways to define a priority measurement for each handle.

- Based on the measure  $P_i$ , ( $i = 1, 2, \dots, n$ ) choose the best  $m-1$  handles, i.e.,  $i$ 's which have larger values of  $P_i$ .

Following is the algorithm to implement the above ideas:

## ALGORITHM

### Step 1.

To compute  $P_i$ , consider vector  $V_i = (x_{1i}, x_{2i}, \dots, x_{ki})$ ,

- a. Make a stack of all  $k$  elements of  $V_i$ .

## NRL REPORT 8382

- b. Set a test element, TELMNT = top element of stack and set COUNT = 1.
- c. Replace the top element of the stack by the last element and, set k = k-1; if k < 1, go to substep e.
- d. Restack the k elements to check that the top element = TELMNT.
  - If it does, COUNT = COUNT + 1; then go to substep c.
  - If it does not, then
    - { If COUNT > 1, then  $P_i = P_i + COUNT * COUNT$  and COUNT = 1. TELMNT = top element of the stack; go to substep c } .
- e. Include the last group's population count in  $P_i$ .

If COUNT > 1, then  $P_i = P_i + COUNT * COUNT$ .

### Step 2.

Using STEP 1, compute all  $P_i$ 's for  $i = 1, 2, \dots, n$ . Store handle numbers in an array, such as  $[c(i) = i, i = 1, \dots, n]$ .

### Step 3.

Sort array P in descending order, and while moving the elements of P during sort, move elements of c also in the same fashion.

For generating  $GH_m$  codes, choose handles in the first  $(m - 1)$  positions of array c, which correspond to the best  $(m - 1)$  values of  $P_i$ ,  $i = 1, 2, \dots, n$ .

Once the set of handles has been selected, the GH encoding is unique.

For example, let point set  $S = \{(3,1,1), (5,1,1), (1,1,2), (4,1,2), (6,2,3)\}$ . Using the previous algorithm, the measure of priority,  $P_i$  for  $i = 1, 2, 3$  are:  $P_1 = 0$ ,  $P_2 = 16$ ,  $P_3 = 8$ . Based on the best values of  $P_i$ , we choose handle set  $(x_2, x_3, x_1)$  and with respect to this set of handles ( $GH_1$ ) is  $\{(1,1,1;2,3,6)\}$ .  $GH_2$  is  $\{(1;1,1;2,5), (2;3,6;6)\}$ .  $GH_3$  is  $\{(1,1;3;5), (1,2;1;4), (2,3;6;6)\}$ .  $GH_4$  is  $\{(1,1,3), (1,1,5), (1,2,1), (1,2,4), (2,3,6)\}$ .

## EXPERIMENTAL RESULTS

The previous algorithm was implemented on an IBM/370 in FORTRAN; a listing of the program is given in Appendix A. The data for the program were random numbers with normal distribution and standard deviation, a number for each column vector  $V_i$  was also a random number with uniform distribution.

The selected set of handles by the previous method was used to generate  $GH_m$  encoded tuples, and their number was counted for a different number of point set and dimensions of space. To find the optimal  $GH_m$  encoding, great effort was taken, and the  $GH_m$  codes with minimum number of  $GH_m$  tuples was taken as the optimal  $GH_m$  encoding. (See Tables 1, 2, and 3.)

Few other heuristic approaches were tested to select the proper set of handles to generate optimal GH encoding, but the previous method has shown the best results and will be used in the next optimization problem.

## PROBLEM 2

From the experimental results we know that the smaller the value of  $m$  (length of handles) the smaller the number of  $GH_m$  encoded tuples for a point set  $S$ , but at the same time such hypercubes tend to be sparse. Therefore, to optimize GH codes for a given

threshold density  $t$ , find a set of handles with minimum length  $m$ , so that the resultant hypercubes have densities no less than theshold density,  $t$ .

Two special cases can be solved immediately. If  $t = 0$ , then we can select  $m = 1$ , so that a single n-dimensional hypercube is generated, and  $GH_1$  becomes the optimum GH encoding. If  $t = 1.0$ , then all the hypercubes must have unit density, and we can select  $m = n + 1$  so that the original point set  $S$  becomes the optimum GH encoding. For other values of  $t$ ,  $m$  should fall between 1 and  $n + 1$ .

## NRL REPORT 8382

**ALGORITHM**

The algorithm optimize GH encoding for a given threshold density.

**Step 1.**

Start with  $m = 1$ ;

generate  $GH_1$  codes, which is one hypercube. If the density of this hypercube is  $\geq$  threshold density, then this is the optimum GH encoding, and go to Step 7,

otherwise, set  $m = m + 1$ .

**Step 2.**

By using the previous heuristic method discussed in Problem 1, choose a set of handles which will generate the optimal  $GH_m$  encoding for a given  $m$ .

Set a flag = 0; and

$NUM = 0$ , where  $NUM$  will be the number of  $GH_m$  encoded tuples with respect to the chosen handle vector of length  $m$ .

**Step 3.**

a. Generate the next hypercube with respect to the above chosen handle vector and compute its density.

b. If density of this hypercube  $>$  threshold density, and

if the number of points in this hypercube  $> 1$ , then

{ include this hypercube in optimal GH encoding.

$NUM = NUM + 1$ ; and

delete the points included in this hypercube from the original point set. }

c. If the density of this hypercube  $<$  threshold density, then set the flat = 1

**Step 4.**

Repeat Step 3 until all the points in point set have been considered once.

**Step 5.**

If the number of points in remaining point set = 0 then go to Step 7.

If (number of points in point set = 1 or

NUM  $\leq 0$  and flag = 0), then go to Step 6.

If (NUM  $\leq 0$  and flag = 1), then  $m = m + 1$ .

Go to Step 2.

**Step 6.**

Generate  $GH_m$  encoded tuples with respect to the last handle vector of length  $m$ .  
Each  $GH_m$  encoded tuple is included in the optimal GH encoding.

**Step 7.**

Stop.

As an illustration, if point set  $S = \{(3,1,1),(5,1,1),(1,1,2),(4,1,2),(6,2,3)\}$  and threshold density = 50% (0.5), then with the previous algorithm, optimal encoding is attended as  $\{(1;1,2;2,5), (2;3,6;3,6)\}$  and the density of each hypercube is  $\geq 50\%$ .

## EXPERIMENTAL RESULTS

The previous algorithm also was implemented on an IBM/370 in FORTRAN. A listing of the program is given in Appendix B. The test data were again random numbers.

The results are in Tables 4, 5, and 6.

## DISCUSSION

In this section, some interesting applications of the generalized GH encoding technique are discussed.

Reference 1 suggests that a relational file  $R$  can be characterized by a logical expression  $E$ , so that every  $n$ -tuple  $(x_1, x_2, \dots, x_n)$  in  $R$  satisfies this logical expression.

The generalized GH encoding technique can be used to find a suitable logical expression characterizing a relational file.

For example, if  $S$  is as given in the Generalized Hypercube Encoding section of this report and  $m = 1$ , then  $GH_1 = \{(1,1,1;2,3,6)\}$  and the corresponding logical expression is  $(1 \leq x_1) \& (1 \leq x_2) \& (1 \leq x_3) \& (x_1 \leq 2) \& (x_2 \leq 3) \& (x_3 \leq 6)$ ;

when  $m = 2$ , then  $GH_2 = \{(1;1,1;2,5), (2;3,6;3,6)\}$  and the corresponding logical expression is  $(x_1 = 1) \& (1 \leq x_2) \& (1 \leq x_3) \& (x_3 \leq 5) \vee ((x_1 = 2) \& (x_2 = 3) \& (x_3 = 6))$ , thus, each GH encoding corresponds to a logical characteristic expression for the relational file.

In addition to applications in database characterization, the previously described technique also can be applied in clustering analysis where clusters are described by hypercubes with handles. Thus optimization technique will generate optimal encoding for the clusters.

A third application can be the description of n-dimensional pictures, which will have a practical significance in computer graphics and image processing applications.
